To test Ho: rho = 0 against H1: rho ≠ 0, reject Ho if |r| > CV. Note: if we can reject Ho then the model is useable.

Least Squares Regression

$\bar{X} = \Sigma X/n \qquad \bar{Y} = \Sigma Y/n$

$SS_{XX} = \Sigma(X^2) - (\Sigma X)^2/n$

$SS_{YY} = \Sigma(Y^2) - (\Sigma Y)^2/n$

$SS_{XY} = \Sigma(XY) - (\Sigma X)(\Sigma Y)/n$

$\beta_1' = SS_{XY} / SS_{XX}$ (slope)

$\beta_0' = \bar{Y} - \beta_1\bar{X}$ (intercept)

$Y' = \beta_0' + \beta_1'X$

$r = SS_{XY} / \sqrt{SS_{XX}SS_{YY}}$

Showing $P(\chi^2 \geq CV) = \alpha$

Test for Goodness-of-Fit

$$\chi^2 = \Sigma \left[\frac{(O - E)^2}{E} \right]$$

Use df = clms-1

Reject Ho: fit as stated

if $\chi^2 > CV$

Test for Independence

$$E = \frac{(\text{row total}) * (\text{clm total})}{(\text{grand total})}$$

Use df = (rows-1) * (clms-1)

Reject Ho: independent

if $\chi^2 > CV$
